Application				Data	
Transport			TCP	Data	
Internet		IP	TCP	Data	
Data Link	Eth	IP	TCP	Data	Eth
Physical					

11100100101010101111000001110101010111

Encapsulation (source: [1])

- Example: Host A is trying to request a web page using HTTP

  – Encapsulation proc...

    - **Step 1.** The HTT... ...tion generates the information, represented as HTTP "data" i... ...mple

    - **Step 2.** On the host, the TCP/IP implementation would detect that HTTP uses TCP at the transport layer and will send the HTTP data to the transport layer for further handling. The protocol at the transport layer, TCP, will create a TCP header, and will send it to the next layer, the Internet layer, for further processing. The TCP header plus the payload forms a TCP segment

    - **Step 3.** The Internet layer receives the TCP information, attaches an IP header, and encapsulates it in an IP packet. The IP header will contain information to handle the packet at the Internet layer

- **Step 4.** The IP packet is then passed to the link layer for further processing. The TCP/IP stack detects that it needs to use Ethernet to transmit the frame to the next device. It will add an Ethernet header and trailer and transmit the frame to the physical network interface card (NIC), which will take care of the physical transmission of the <u>frame</u>

– Decapsulation process

- When the information arrives to the destination, the receiving host will start from the bottom of the TCP/IP stack by receiving an Ethernet frame

- The link layer of the destination host will read and process the header and trailer, and then pass the IP packet to the Internet layer for further processing

- The same process happens at the Internet layer, and the TCP segment is passed to the transport layer, which will again process the TCP header information and pass the HTTP data for final processing to the HTTP application

THE UNIVERSITY OF MELBOURNE
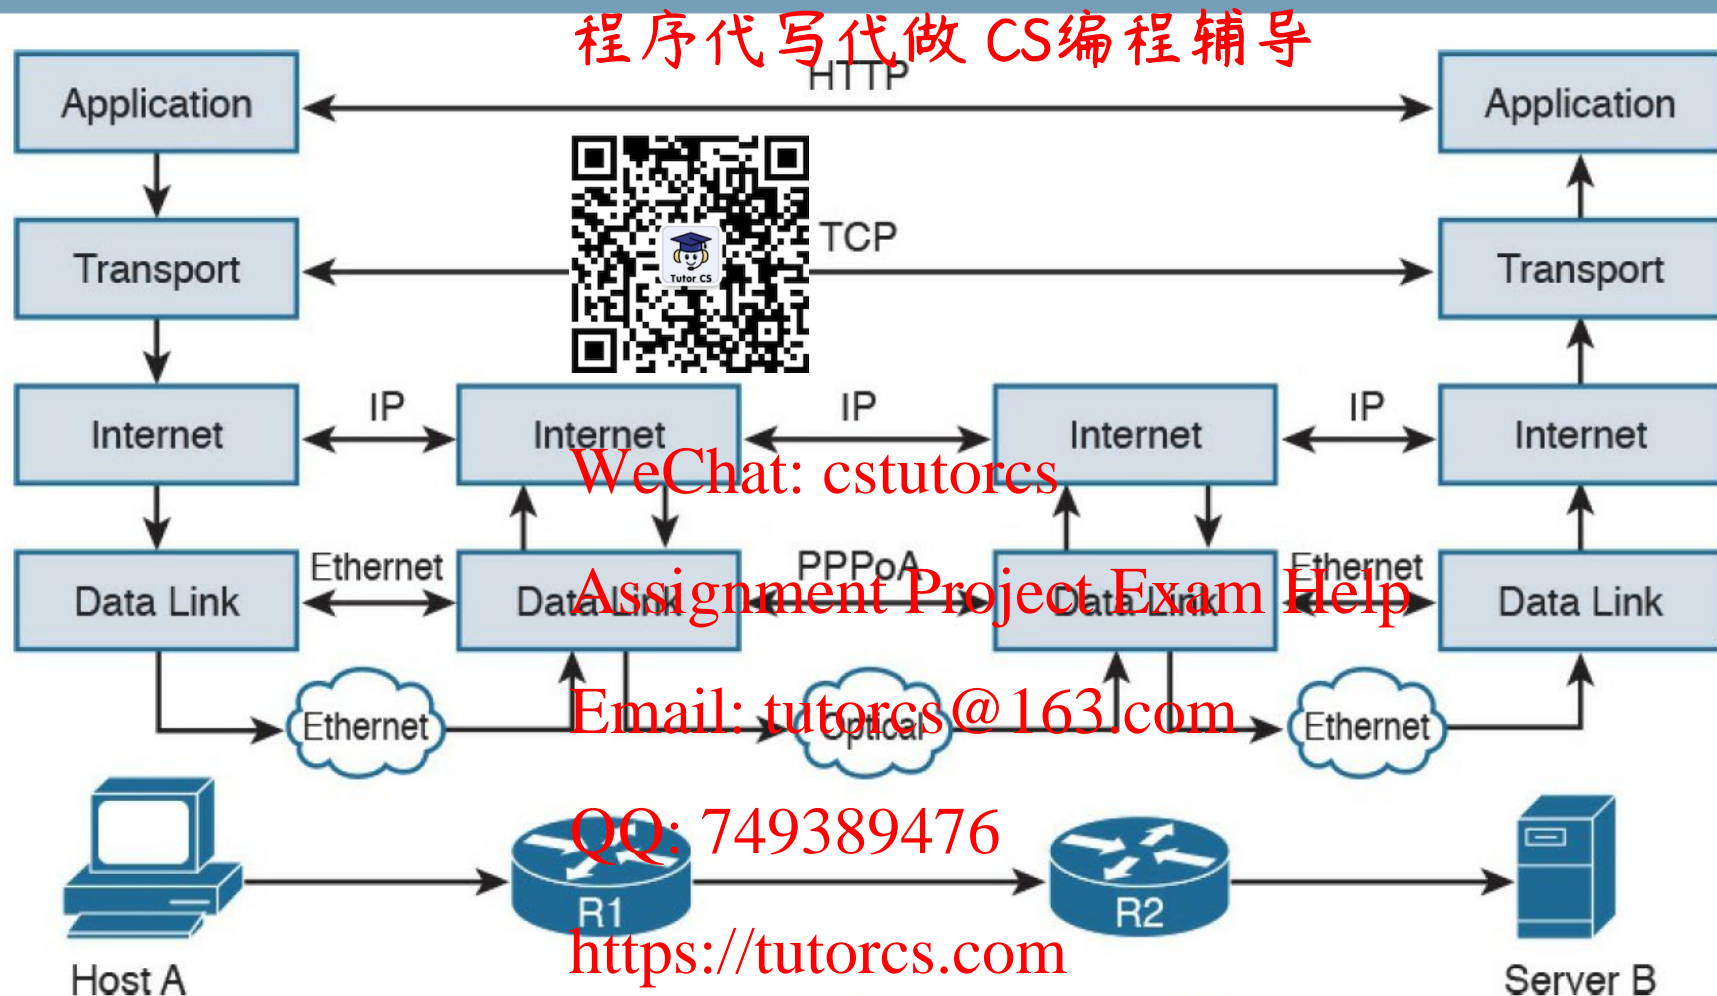

Example: Host A is requesting a webpage via HTTP from Server B (Source: [1])

- **Step 1.** The HTTP application on Host A will create an HTTP Application message th[ ]es an HTTP header and the contents of the request in the paylo[ ]will be encapsulated up to the link layer, and transmitted over th[ ] R1

- **Step 2.** The R1 link layer will receive the frame, extract the IP packet, and send it to the IP layer. Because the main function of the router is to forward the IP packet, it will not further decapsulate the packet. It will use the information in the IP header to forward the packet to the best next router, R2. To do that, it will encapsulate the IP packet in a new link layer frame and send the frame on the physical link toward R2

- **Step 3.** R2 will follow the same process that R1 followed in step 2 and will send the IP packet encapsulated in a new Ethernet frame to Host B

- **Step 4.** Server B's link layer will decapsulate the frame and send it to the Internet layer

- **Step 5.** The Internet layer verifies that the packet is destined to Server B itself by looking into the IP header information. It strips the IP header and passes the TCP segment to the transport layer

- **Step 6.** The transport layer uses the port information included in the TCP header to determine to which application to pass the data

- **Step 7.** The application layer, the web service, finally receives the request and may decide to respond. The process will start again, with the web service creating some data and passing it to the HTTP application layer protocol for handling
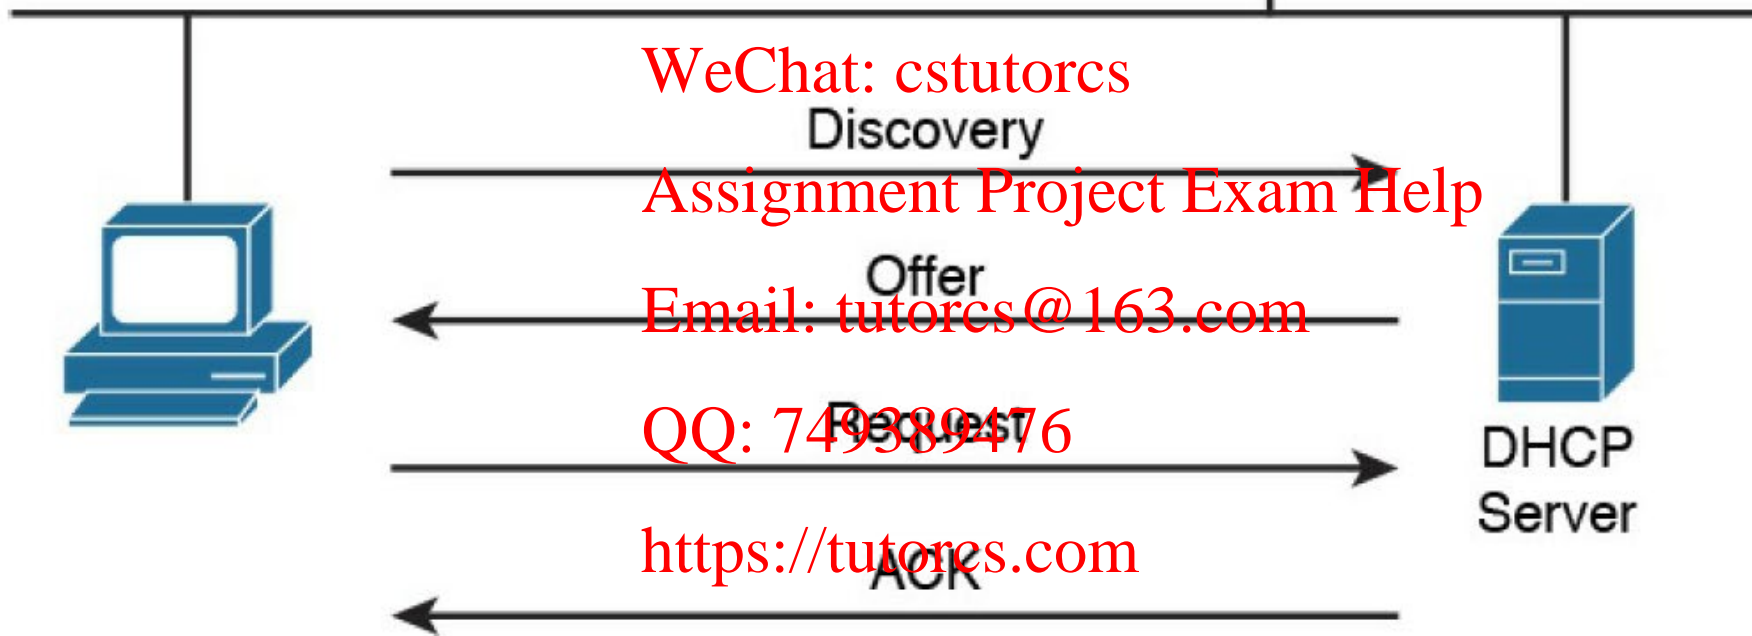

Basic DHCP IP Address Assignment Process (Source: [1])

- **Step 1.** When a host first connects to a LAN, it does not have an IP address. It will send a DHCPDISCOVERY packet to discover the DHCP servers within a LAN. In a LAN there could be more than one DHCP server

- **Step 2.** Each DHCP server responds with DHCPOFFER message

- **Step 3.** The client receives several offers, picks one of them, and responds with a DHCPREQUEST

- **Step 4.** The DHCP server that has been selected responds to the client with a DHCPACK to confirm the leasing of the IP address
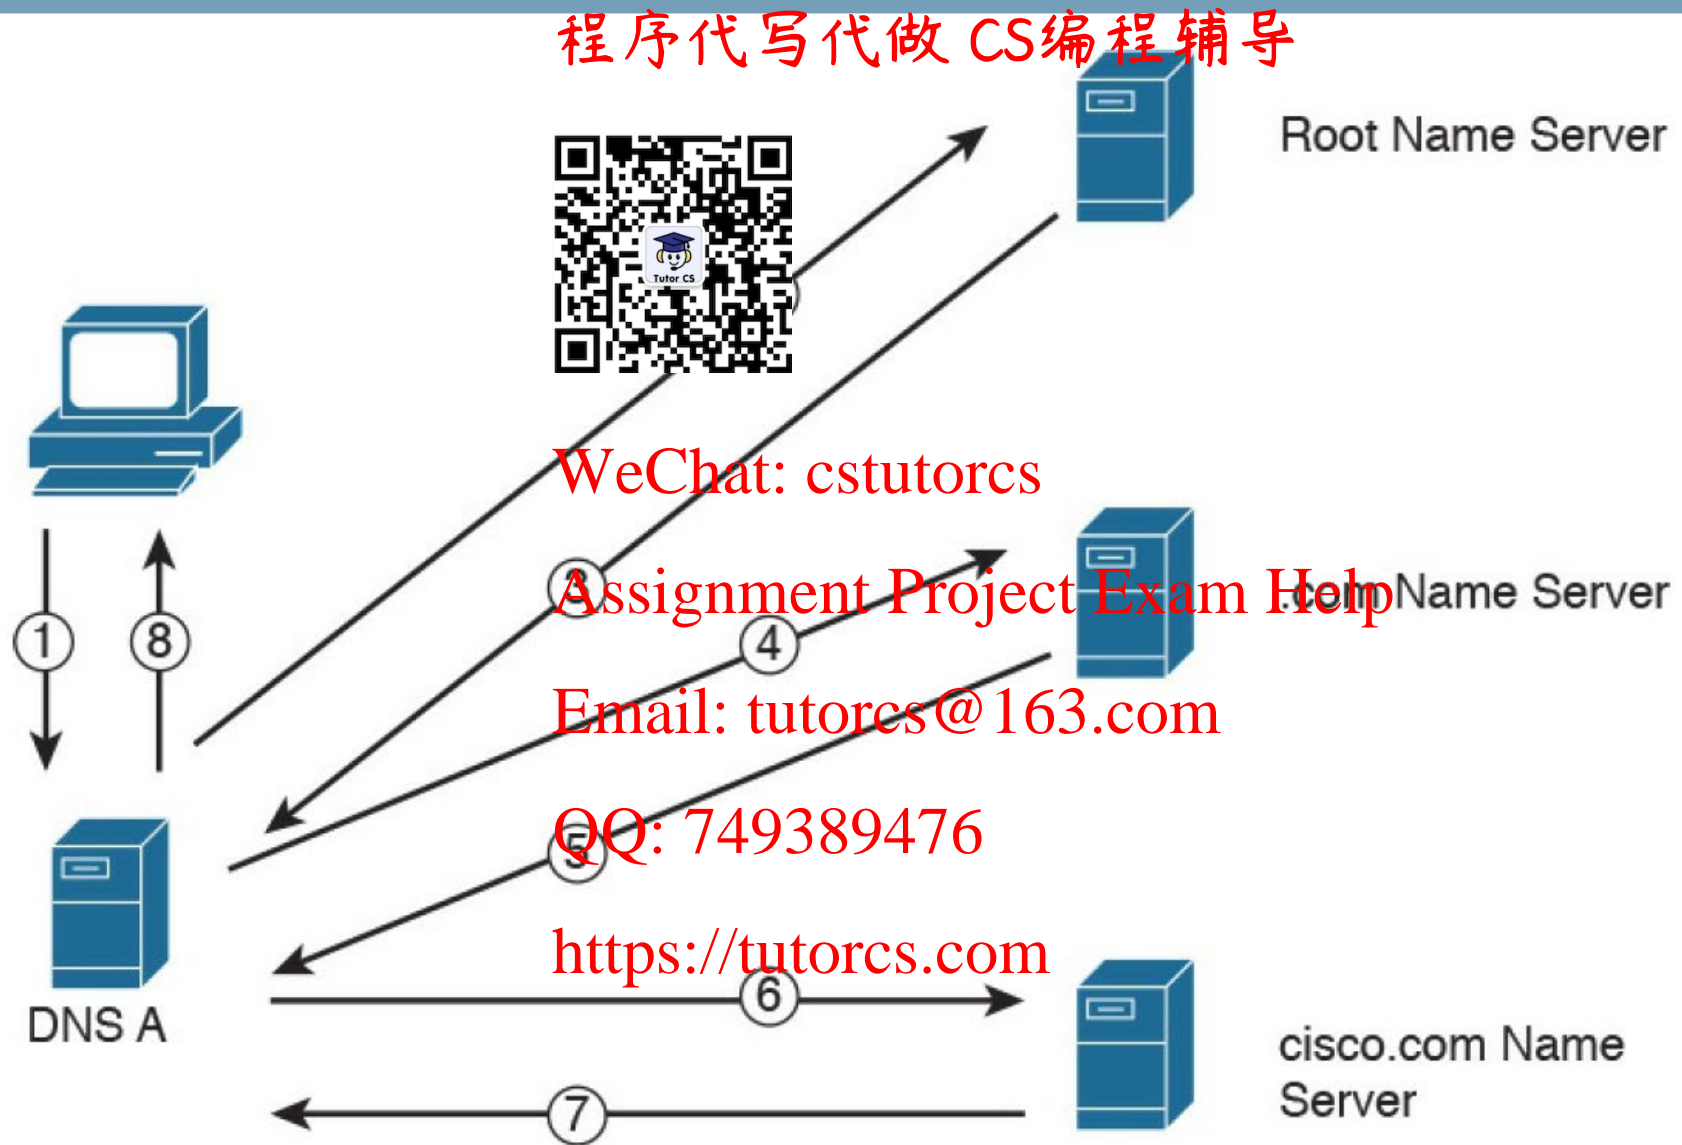

DNS Resolution (Source: [1])

- **Step 1.** Host A sends a recursive DNS query for a type A record to resolve www.cisco.com ☐☒☐☐ DNS server, DNS A

- **Step 2.** DNS A checks ☐☒☐☐ ache but does not find the information, so it sends an iterative DNS query to the root DNS server, which is authoritative for all of the internet

- **Step 3.** The root DNS server is not authoritative for that host, so it sends back a referral to the .com DNS server, which is the authoritative server for the .com domain

- **Steps 4 and 5.** The .com DNS server performs a similar process and sends a referral to the cisco DNS server

- **Steps 6 and 7.** The cisco DNS server is the DNS authoritative server for www.cisco.com, so it can reply to DNS A with the information

- **Step 8.** DNS A receives the information and stores it in its DNS cache for future use
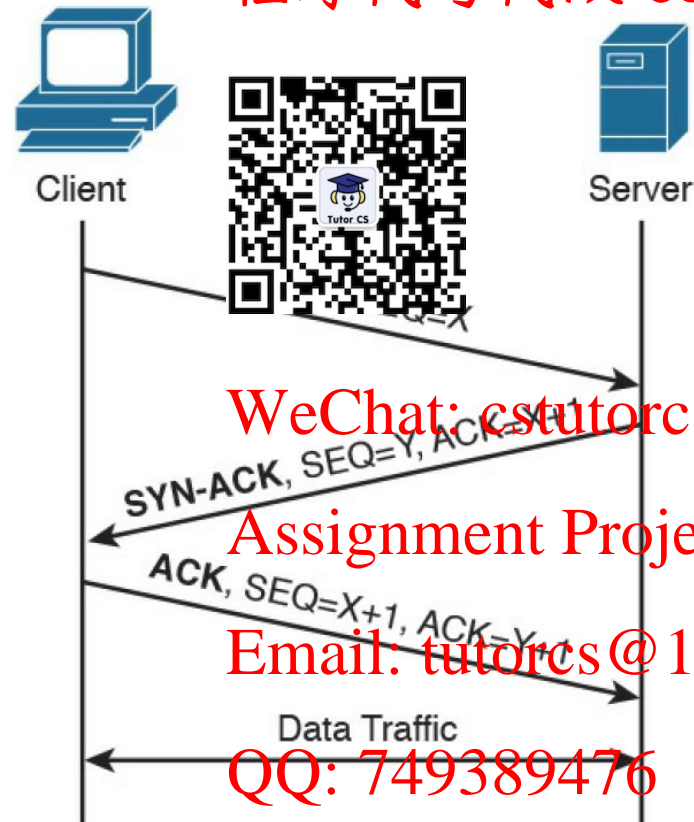

TCP Three-way Handshake (Source: [1])

- **First packet (SYN):** The client starts the process of establishing a connection with a server by sending a TCP segment that has the SYN bit set to 1, in order to signal to the peer that it wants to synchronize the sequence numbers and establish the connection. The client also sends its initial sequence number, which is a random number X set by a client

- **Second packet (SYN-ACK):** The server responds with a SYN-ACK packet where it sends its own request for synchronization and its initial sequence number. Within the same packet, the server also sends the acknowledgment number X+1, acknowledging the receipt of a packet with the sequence number X and requesting the next packet with the sequence number X+1

- **Third packet (ACK):** The client responds with a final acknowledgment, requesting the next packet with the sequence number Y+1

Attacks that include the discovery process used to gain information about the network, users, and victims

- **Basic port scan**: Involves a predetermined TCP/UDP port by sending a specifically configured packet contains the port number of the port that was selected

- **TCP scan**: A TCP-based scan of a series of ports on a machine to determine port availability, e.g.,
  - *If a port on the machine is listening, then the TCP "connect" is successful in reaching that specific port*

- **UDP scan**: Because UDP is a connectionless protocol and does not have a three-way handshake like TCP, the UDP scans have to rely on ICMP "port unreachable" messages to determine if the port is open, e.g.,
  - *When the scanner sends a UDP packet and the port is not open on the victim, the victim's system will respond with an ICMP "port unreachable"*

- **Stealth scan**: Designed to go undetected by network auditing tools

Attacks that leverage the weakest link, which is the human user

- **Phishing**: Where the attacker presents a link that looks like a valid, trusted resource to a user. When the user clicks it, he is prompted to disclose confidential information such as his username and password

- **Pharming**: The attacker uses this technique to direct a customer's URL from a valid resource to a malicious one that could be made to appear as the valid site to the user. From there, an attempt is made to extract confidential information from the user

程序代写代做 CS编程辅导

- **Malvertising**: The of incorporating malicious ads or websites, which results in users' browsers being inadvertently redirected to sites hosting malware

- Backdoors
  - A backdoor application can be installed by the attacker to either allow future access or collect information to use in further attacks
  - Many backdoors are installed by users clicking something without realising that the link they clicked or the file they opened is a threat
  - Backdoors can also be implemented as a result of a virus, worm, or malware

- Code Execution
  - When threat actors gain access to a system, they also might be able to take several actions. One of the most devastating actions available to an attacker is the ability to execute code within a device
  - Code execution could result in an adverse impact to the confidentiality, integrity, and availability of the system or network

Attackers place themselves in line between two devices that are communicating, with the intent of performing reconnaissance or manipulating the data as it moves between the devices

- Main purpose: Eavesdrop

- Where can it occur
  - At OSI Layer 2, the attacker spoofs Layer 2 MAC addresses to make the devices on a LAN believe that the Layer 2 address of the attacker is the Layer 2 address of its default gateway

  - **ARP Cache Poisoning**
    - Attacking hosts, switches, and routers connected to Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet

程序代写代做 CS编程辅导

– At OSI Layer 3, the attacker places a rogue router on the network and then the other routers into believing that this new router has a path. This could cause network traffic to flow through rogue router and again allow the attacker to steal network data

WeChat: cstutorcs

– On endpoint, the attacker compromises the victim's machine and installs malware that can intercept the packets sent by the victim and send them to the attacker

- MITM: trick A and B into believing that they are communicating with each other

Man in the middle

https://beaglesecurity.com/blog/article/man-in-the-middle-attack.html
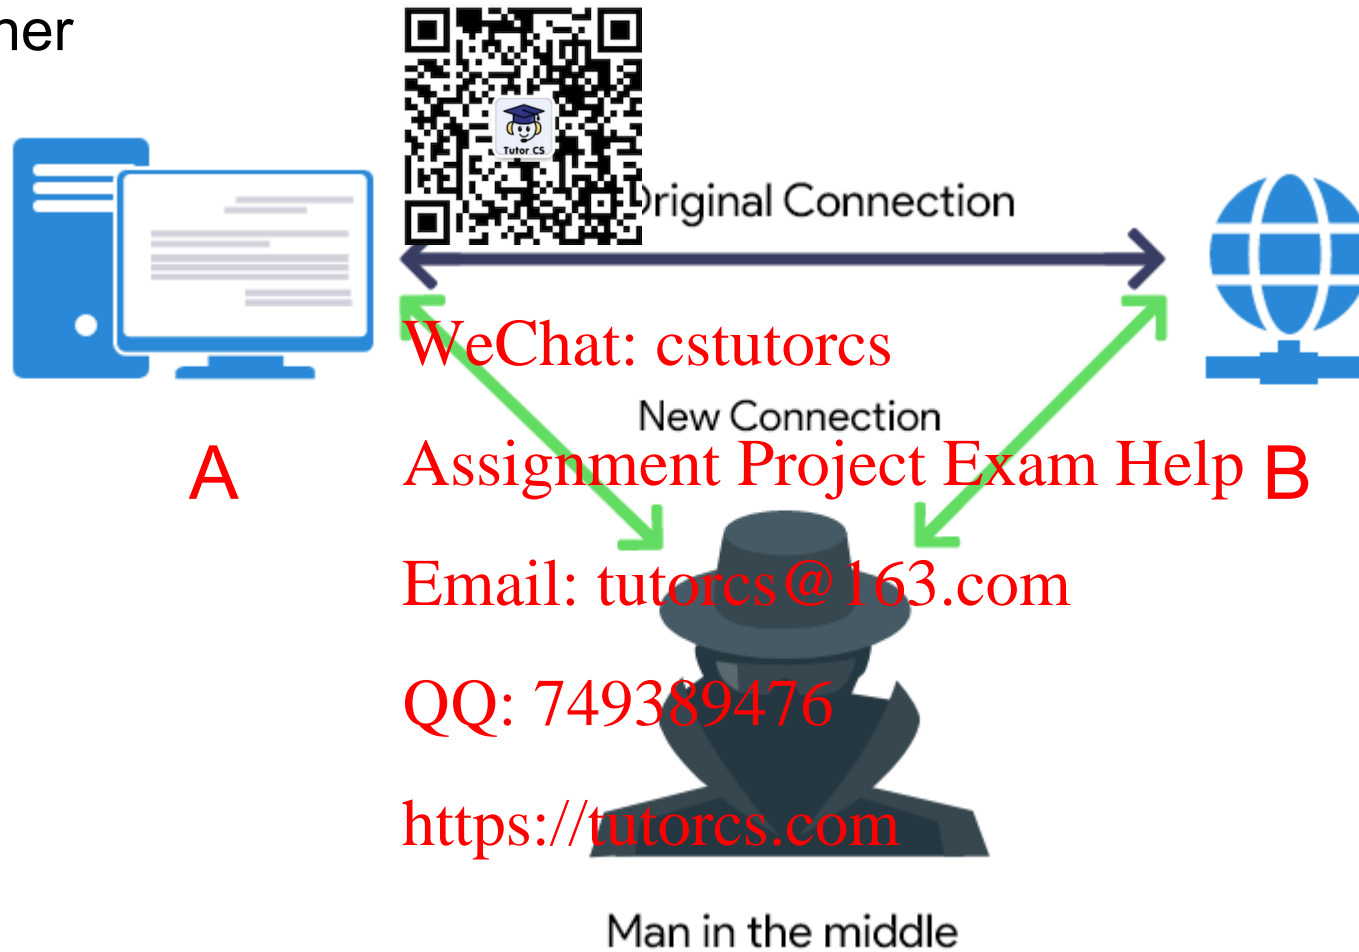

- The attacker has a C2 server, with a domain name (badsite.c̶o̶m̶) pointing to that server.

- The attacker infects a host with malware, and let the host query the domain badsite.com.

- When the DNS resolver routes the query, it creates a tunnel from the attacker to the infected host.

DNS Resolution (Source: [1])

- Inbound DNS traffic can carry commands to the malware
- Outbound traffic can exfiltrate sensitive data or provide responses to the malware operator's requests
